

Unit-2

TESTING OF HYPOTHESIS:

⊗ Hypothesis → Hypothesis is an assumption or claim or statements.
By the help of testing of hypothesis we are able to test whether the hypothesis is true or not.

⊗ Types of hypothesis:

a) Null Hypothesis (H_0) → Null hypothesis is symbolized by H_0 .
Null hypothesis contains sign either $(=)$ or (\leq) or (\geq) .

⇒ Null hypothesis question मा किसका हूँदा mainly = भावी condition आउदा question मा. almost भने \leq sign use गर्ने & at least भने \geq sign use गर्ने,

For e.g. Null Hypothesis (H_0): $\mu = 30$.

i.e., the population mean is 30.

Generally सब question मा = condition हुँदा

b) Alternate Hypothesis (H_1) → It is symbolized by H_1 and
it contains the sign either (\neq) or $(<)$ or $(>)$.

⇒ Question को आवारमा हालि sign select गर्ने,
i.e., On the basis of question we use alternate hypothesis
either $\mu \neq$ (represents two-tailed test)
or, $\mu >$ (represents one-tailed test)
or $\mu <$ (represents one-tailed test). (केही condition नभए question मा $\mu \neq$ use गर्ने)

Note: According to question first we write null hypothesis then
we select alternate (झेचि) hypothesis as below:-

~~alternate of $= \neq$ (for two-tailed test)~~

~~alternate of $<$ $\mu >$ (one-tailed i.e., right tailed test)~~

~~alternate of \geq $\mu <$ (one-tailed i.e., left tailed test)~~

For e.g. $\mu \neq 30$ i.e., Population mean is different than 30.

$\mu < 30$ i.e., Population mean is less than 30.

$\mu > 30$ i.e., Population mean is greater than 30.

Remember: assumption जस्तै पनि population को लागि हुँदा भने test statistics मा गर्ने /

④ Concept of two tailed, one tailed left & one tailed right:

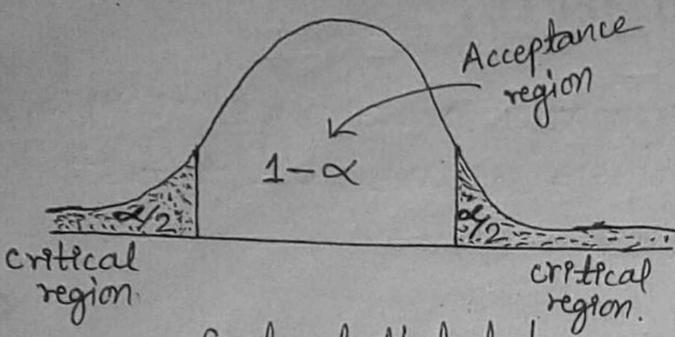

fig. two tailed tailed

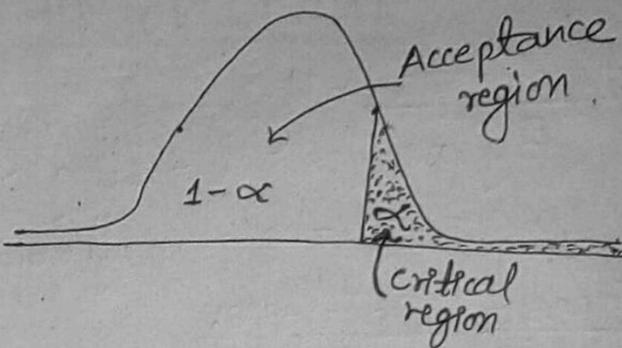

fig. One tailed right

Note: Critical region is also called rejection region

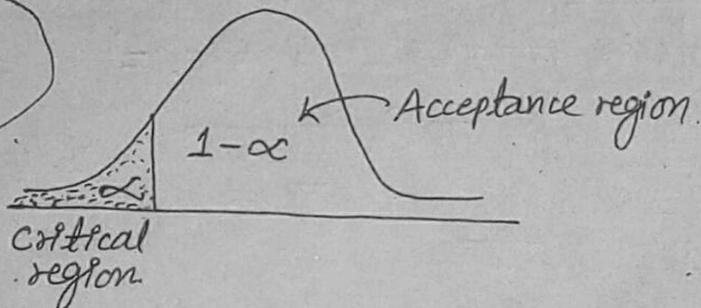

fig. One tailed left

⑤ Errors while making decision:

Decision	Actual situation	
	H_0 is true	H_0 is false
H_0 is accepted	Correct decision ($1-\alpha$)	Type II nd Error $\beta = P(\text{Type II}^{\text{nd}} \text{ Error})$
H_0 is rejected	Type I st Error $\alpha = P(\text{Type I}^{\text{st}} \text{ Error})$	Correct decision ($1-\beta$)

Note: Level of significance
(α) Question सा किसीको भरने याइ value use नहीं लगा generally we use 5%.

Here,
 α = level of significance
 $= P(H_0 \text{ is rejected} / H_0 \text{ is true})$.

So, $1 - \alpha$ = level of confidence
 $= P(H_0 \text{ is accepted} / H_0 \text{ is true})$

& $\beta = P(\text{Type II}^{\text{nd}} \text{ Error})$
 $= P(H_0 \text{ is accepted} / H_0 \text{ is false})$

where P = Probability

$1 - \beta = P(H_0 \text{ is rejected} / H_0 \text{ is false})$.

Q. Steps in testing of Hypothesis:

- 1) Identify the claims. (i.e., Question में को find होने को दिया जाता है) i.e., finding null hypothesis.
- 2) Setting of NULL and Alternate hypothesis. (i.e., Problem to test) (We have already discussed Null and Alternate hypothesis).
- 3). Test statistics:

Test statistics (i.e., calculated value) = $\frac{\text{Sample statistics} - \text{pop}^n \text{ parameter}}{\text{Standard error}}$

- 4). Critical Value: (Tabulated value at α level of significance with degree of freedom)

\Rightarrow The no. of independent variates which make up statistic is called degree of freedom. It is simply denoted by d.f.
- 5) Decision: If calculated value is greater than critical value or tabulated value then, H_0 is rejected. i.e., H_1 will be accepted.
 - If calculated value is less or equal to critical value then H_0 is accepted. i.e., H_0 will be rejected.
- 6) Conclusion on the basis of decision (i.e., Interpretation of result).

Q1. A sample of size 400 was drawn and the sample mean was found to be 99. Test whether this sample could have come from a normal population with mean 100 and standard deviation 8 at 5% level of significance.

Solution:

Given,
 Sample size (n) = 400
 Sample mean (\bar{x}) = 99
 Population mean (μ) = 100
 Standard deviation (σ) = 8.
 Level of significance (α) = 5%
 $= 0.05$

We have already discussed about all these types of notations like n , N , s , μ etc. in 1st chapter revise them

Now,
Problem to test

Null Hypothesis (H_0): $\mu = 100$ i.e., popⁿ mean is 100.

Alternate Hypothesis (H_1): $\mu \neq 100$
 i.e., population mean is not equal to 100.

Test Statistics:-

$$Z_{\text{cal}} = \frac{\bar{x} - \mu_0}{\sigma / \sqrt{n}} = \frac{99 - 100}{8 / \sqrt{400}} = -2.5$$

Z_{cal} true Z_{tab}

$$\therefore |Z_{\text{cal}}| = 2.5$$

Critical value:-

The tabulated value of Z at 0.05 level of significance
 $Z_{0.05} = 1.96$ (two-tailed test)

Decision:

Since $|Z_{\text{cal}}| = 2.5 > Z_{\text{tab}} = 1.96$.
 $\therefore H_0$ is rejected. i.e., H_1 is accepted.

from value table
given at back of
book page no. 309

Conclusion:

Hence we can conclude that the population mean is not equal to 100.

Q2. A random sample of 100 pen drive selected from a batch of 2000 pen drives shows that the average thickness of the pen drive is 0.354 with a standard deviation 0.048. Are the samples from the lot having average thickness 0.35?

Solution

Here, Sample size (n) = 100

Population size (N) = 2000

Sample mean (\bar{x}) = 0.354

Sample SD (s) = 0.048

Population mean (μ_0) = 0.35

Problem to test:

Null Hypothesis (H_0): $\mu_0 = 0.35$

i.e., average thickness of pen drive is 0.35

Alternate Hypothesis (H_1): $\mu_0 \neq 0.35$ (two-tailed)

i.e., average thickness of pen drive is not 0.35

Test Statistics

$$Z_{\text{cal}} = \frac{\bar{x} - \mu_0}{\frac{s}{\sqrt{n}}} = \frac{0.354 - 0.35}{\frac{0.048}{\sqrt{100}} \sqrt{\frac{2000-100}{2000-1}}} = \frac{0.004}{0.0047} = 0.854$$

We use this formula in case where N (Capital N) and S are given.
S.E may change according to question we already read S.E types in unit 1
standard error

Critical Value:

Let $\alpha = 5\%$ be the level of significance then critical value for two tailed test $Z_{0.05} = 1.96$

Decision: Here, $|Z_{\text{cal}}| = 0.854 < Z_{\text{tab}} = 1.96$. So we accept H_0 at 5% level of significance. i.e. H_1 is rejected.

Conclusion: Sample are from lot having average thickness of pen drive 0.35.

Q3: If the mean breaking strength of a copper wire is 575 lbs with s.d. of 8.3 lbs. How many large sample must be used in order that there be one chance in 100 that the mean breaking strength of the sample is less than 572 lbs?

Solution:

Here, Population mean (μ_0) = 575

Population SD (σ) = 8.3

$P(\text{mean breaking strength} < 572) = \frac{1}{100}$

Sample mean (\bar{x}) = 572

$\alpha = 1\%$

Problem to test

Null Hypothesis (H_0): $\mu_0 = 575$

i.e. Mean breaking length of copper wire is 575 lbs.

Alternative Hypothesis (H_1): $\mu_0 < 575$ (one-tail left)

i.e. Mean breaking length of wire is less than 575 lbs.

Test statistic

$$Z_{\text{cal}} = \frac{\bar{x} - \mu_0}{\frac{\sigma}{\sqrt{n}}} = \frac{572 - 575}{\frac{8.3}{\sqrt{n}}} = -0.3614 \sqrt{n}$$

$$\text{i.e., } |Z_{\text{cal}}| = 0.3614 \sqrt{n}$$

Critical value

At $\alpha = 1\%$

Here, $= 0.01$ critical value for one tailed test is $Z_{tab} = 2.32$

$$0.3614 \sqrt{n} = 2.32$$

$$\text{or, } \sqrt{n} = \frac{2.32}{0.3614} = 6.419$$

$$\text{or, } n = 41.2$$

$$\text{or, } n \approx 41$$

n तो Z_{tab} का
 critical value = tabulated
 value

Q4. An ambulance service claims that it takes on the average 8.9 minutes to reach to its destination in emergency calls.

To check the claim, the agency which licenses ambulance services has them timed on 50 emergency calls getting a mean of 9.3 minutes with S.D. of 1.6 minutes. What can they conclude at the level of significance $\alpha = 0.05$? Use the confidence limit to make conclusion.

Solution: (इसको तरने नदियों के लिए सीधा विकास है गणित (Since $S = \sigma$) या असर गणित).

Here, Population mean(μ) = 8.9, Sample size(n) = 50, Sample mean(\bar{x}) = 9.3, Sample S.D. (s) = 1.6, level of significance (α) = 0.05.

Problem to test:

H_0 : Average time taken by ambulance to reach destination is 8.9 min ($\mu = 8.9$)

H_1 : Average time taken by ambulance to reach destination is not 8.9 min ($\mu \neq 8.9$). (Two-tailed).

Critical value

At $\alpha = 0.05$ critical value for two tailed test is $Z_{tab} = 1.96$

The limits of acceptance region for $\bar{x} = \mu + Z_{tab} \frac{s}{\sqrt{n}} = 8.9 + 1.96 \times \frac{1.6}{\sqrt{50}}$

Taking + sign, $\bar{x} = 9.343$ & taking - sign, $\bar{x} = 8.457$

$$= 8.9 \pm 0.443$$

Decision: 9.3 lies between 8.457 and 9.343. So, H_0 is accepted.

Conclusion: The claim of ambulance service that it takes on average 8.9 minutes to reach destination is true.

Q. Testing of Hypothesis by using P-value approach:

By using Probability value (P-value) approach we can also test the hypothesis. In P-value approach P-value can be obtained as follows:-

For one-tailed test (Either left tailed or right tailed):

$$P\text{-value} = 0.5 - P(0 \leq x \leq z_{\text{cal}}).$$

For two-tailed test:

$$P\text{-value} = 2 \{ 0.5 - P(0 \leq x \leq z_{\text{cal}}) \}$$

→ For making decisions p-value is compared with level of significance then, if p-value is $\leq \alpha$ then H_0 is rejected and if P-value is $> \alpha$ then H_0 is accepted.

Q1. The mean life time of 400 laptop cells produced by a company is found to be 1570 hours with a standard deviation of 150 hours. Test the hypothesis that the mean life of the laptop cells produced by the company is 1600 hours against the alternative hypothesis that is greater than 1600 hours at 1% level of significance.

Solution:

Given, Sample size (n) = 400, mean life time (\bar{x}) = 1570 hours.

St. dev. (σ) = 150 hours, Popn life time (μ) = 1600 hours
level of significance = 1% = 0.01.

Problem to test

Null Hypothesis (H_0): $\mu = 1600$

Alternate Hypothesis (H_1): $\mu > 1600$

Test statistics

$$z_{\text{cal}} = \frac{\bar{x} - \mu}{\frac{\sigma}{\sqrt{n}}} = \frac{\bar{x} - \mu}{\frac{s}{\sqrt{n}}} = \frac{1570 - 1600}{\frac{150}{\sqrt{400}}} = -4$$

$$\therefore |z_{\text{cal}}| = 4$$

(Since $s = \hat{\sigma}$)

By using P-value approach

Since this is the case of one tailed test. So, P-value
So, $P\text{-value} = 0.5 - P(0 \leq Z \leq Z_{\text{cal}})$ or $0.5 - P(0 \leq Z \leq 4)$
 $= 0.5 - 0.4997$
 $= 0.0003$

Decision: P-value $= 0.0003 < \alpha = 0.01$.
So, H_0 is rejected i.e., H_1 is accepted.

Conclusion: Hence the population mean lifetime of laptop is greater than 1600 hours.

Q. Hypothesis (Test of Significance) of difference between two means:

Problem to test

Null Hypothesis (H_0): $\mu_1 = \mu_2$

i.e., there is no significance difference between two means.

Alternate Hypothesis (H_1): $\mu_1 \neq \mu_2$

i.e., there is significance difference between two means.

OR $\mu_1 < \mu_2$ i.e., first popⁿ mean is less than second popⁿ mean.

OR $\mu_1 > \mu_2$ i.e., first popⁿ mean is greater than second popⁿ mean.

Test Statistics:

$$Z_{\text{cal}} = \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}} = \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}} \quad \left(\text{Since } s_1 = \sigma_1 \text{ and } s_2 = \sigma_2 \right)$$

Q1 In a certain factory there are two independent processes for manufacturing the same item. The average weight in a sample of 250 items produced from one process is found to be 120 gms with a standard deviation of 12 gms, while the other process are 124 and 14 in a sample of 400 items. Is the difference between the mean weights significant at 10% level of significance.
Use p value method.

Solution:

1st Sample

Sample size (n_1) = 250

Sample mean (\bar{X}_1) = 120 gms

Standard deviation (S_1) = 12 gms

2nd Sample

Sample size (n_2) = 400

Sample mean (\bar{X}_2) = 124 gms

Standard deviation (S_2) = 14 gms.

$$\text{level of significance} = 10\% = 0.10$$

Problem to test:

Null Hypothesis (H_0): $\mu_1 = \mu_2$

i.e. there is no significance difference between the two mean weights.

Alternate Hypothesis (H_1): $\mu_1 \neq \mu_2$

i.e. There is significance difference between the two mean weights.

Test Statistics:

$$\begin{aligned}
 Z_{\text{cal}} &= \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{\frac{\sigma_1^2}{n_1} + \frac{\sigma_2^2}{n_2}}} = \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{\frac{S_1^2}{n_1} + \frac{S_2^2}{n_2}}} \quad \left(\begin{array}{l} \text{if } S_1 = \hat{\sigma}_1 \\ \text{if } S_2 = \hat{\sigma}_2 \end{array} \right) \\
 &= \frac{120 - 124}{\sqrt{\frac{12^2}{250} + \frac{14^2}{400}}} \\
 &= -3.874
 \end{aligned}$$

$\therefore |Z_{\text{cal}}| = 3.874$

By using P-value:

$$\begin{aligned}
 \text{P-value} &= 2 \{ 0.5 - P(0 \leq z \leq Z_{\text{cal}}) \} \\
 &= 2 \{ 0.5 - P(0 \leq z \leq 3.874) \} \\
 &\doteq 2 \{ 0.5 - 0.4995 \} \\
 &= 2 \times 0.00005 \\
 &= 0.0001
 \end{aligned}$$

value of 3.874
from table page no. 309

Decision: Since P-value = 0.0001 < $\alpha = 0.10$, So H_0 is rejected.
i.e., H_1 is accepted.

Conclusion: Hence we can conclude that there is significance difference between two mean weights.

Q2. Two research laboratories have independently produced drugs that provide relief to arthritis sufferers. The first drug was tested on a group of 90 arthritis victims and produced an average of 8.5 hours relief with a standard deviation of 1.8 hours. The second drug was tested on 80 arthritis victims producing an average of 7.9 hours of relief with a standard deviation of 2.1 hours. At 5% level of significance does the second drug provide a significantly shorter period of relief?

Solution:

Drug Ist

Sample size (n_1) = 90

Sample mean (\bar{X}_1) = 8.5 hours

Standard deviation (s_1) = 1.8 hours

Drug IInd

Sample size (n_2) = 80

Sample mean (\bar{X}_2) = 7.9 hours

Standard deviation (s_2) = 2.1 hours

level of significance (α) = 5% = 0.05.

Problem to test:

Null Hypothesis (H_0): $\mu_1 = \mu_2$ i.e., the average relief time of both drugs is same.

Alternate Hypothesis (H_1): $\mu_1 > \mu_2$ i.e., first drug provides more relief time than second drug.

Test Statistics:

$$Z_{\text{cal}} = \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}} = \frac{8.5 - 7.9}{\sqrt{\frac{(1.8)^2}{90} + \frac{(2.1)^2}{80}}} = 1.98$$

By using P-value

$$\text{P-value} = 0.5 - P(0 \leq Z \leq Z_{\text{cal}})$$

$$= 0.5 - P(0 \leq Z \leq 1.98)$$

$$= 0.5 - 1.8 = 0.239$$

$$= 0.261$$

$$= 0.261$$

value of 1.98 in
one-tailed table

$$= 0.5 - 0.239$$

$$= 0.261$$

Since one-tailed test
 $\alpha = 5\% = 0.05$
 $\Rightarrow 0.5 - \alpha = 0.5 - 0.05$
 $= 0.45$

Now we see value of
0.45 in one-tailed
probability > table
(inside table) page
no. 310

Decision: Since P-value = 0.261 > $\alpha = 0.05$. So, H_0 is accepted.
i.e., H_1 is rejected.

Conclusion: Hence, The average relief time of both drugs is same.

Q. Hypothesis testing of single population proportion (P):

Problem to test:

Null Hypothesis (H_0): $P = P_0$ (Specified value).

Alternate Hypothesis (H_1): $P \neq P_0$

OR $P < P_0$

OR $P > P_0$

Test Statistics:

$$Z_{\text{cal}} = \frac{p - P}{\sqrt{\frac{PQ}{n}}}$$

where, p = sample proportion.

P = Population proportion.

$$Q = 1 - P$$

n = sample size.

Q1. A coin is tossed 600 times and head appear 320 times, does this result support the hypothesis.

Soln

Given,

$$\text{Population proportion (}P\text{)} = \frac{1}{2}$$

$$\begin{aligned} Q &= 1 - P \\ &= 1 - \frac{1}{2} \\ &= \frac{1}{2} \end{aligned}$$

$$\text{Sample size (}n\text{)} = 600$$

$$\text{sample proportion (}p\text{)} = \frac{320}{600} = 0.533$$

Problem to test:

Null Hypothesis (H_0): $P = \frac{1}{2} = 0.5$

i.e, coin is unbiased.

Alternative Hypothesis (H_1): $P \neq \frac{1}{2} = 0.5$

i.e, coin is not unbiased (i.e, biased).

Test Statistics:

$$\begin{aligned} Z_{\text{cal}} &= \frac{p - P}{\sqrt{\frac{PQ}{n}}} \\ &= \frac{0.533 - 0.5}{\sqrt{\frac{0.5 \times 0.5}{600}}} \\ &= 1.6166 \end{aligned}$$

Critical value:

The tabulated value of Z at 0.05 level of significance

$$Z_{0.05} = 1.96 \text{ (two-tailed test)}$$

Decision: Since $Z_{\text{cal}} = 1.6166 < Z_{0.05} = 1.96$, So, H_0 is accepted.
i.e., H_1 is rejected.

Conclusion: Hence, the coin is unbiased and this result supports the hypothesis.

Q.2 A dice was thrown 9000 times and of these 3220 yielded a 3 or 4. Is this consistent with the hypothesis that the dice is unbiased?

Soln

Given, no. of throws (n) = 9000

no. of times 3 or 4 is obtained (X) = 3220
Sample proportion (φ) = X/n

$$= \frac{3220}{9000}$$

$$= 0.358$$

Problem to test: level of significance (α) = 5% = 0.05.

Null Hypothesis (H_0): $P = \frac{1}{6} = 0.1666$

i.e., the dice is unbiased.

Alternate Hypothesis (H_1): $P \neq \frac{1}{6} = 0.1666$

Test Statistics: i.e., the dice is not unbiased (i.e., biased).

$$Z_{\text{cal}} = \frac{P - \varphi}{\sqrt{\frac{P\varphi}{n}}}$$

$$= 0.358 - 0.1666$$

$$\sqrt{\frac{0.1666 \times 0.8334}{9000}}$$

$$= \frac{0.1914}{0.00393} = 48.7$$

Decision: Since $Z_{\text{cal}} = 48.7 > Z_{0.05} = 1.96$ (i.e., critical value), So, H_0 is rejected.

Conclusion: This is not consistent with the hypothesis that dice is unbiased.

Q3. The coordinator in a college claimed that at least 98% of the students submit their assignment on time. Taking the sample of 250 students, 15 were not submitting assignment in whole semester. Test his claim at 10% level of significance.

Solution:

Given, Sample size (n) = 250

No. of student who do not submitted assignment on time = 15

No. of students who submitted assignment on time = $250 - 15$

\therefore Sample proportion of student who submitted the assignment on time = $\frac{x}{n} = \frac{235}{250} = 0.94$

level of significance (α) = 10% = 0.10

Problem to test:

Null Hypothesis (H_0): $P \geq 0.98$

i.e. at least 98% of student submitted their assignment on time.

Alternate Hypothesis (H_1): $P < 0.98$

i.e. Student submitted their assignment on time is less than 98%.

Test Statistics:

$$Z_{\text{cal}} = \frac{p - P}{\sqrt{\frac{PQ}{n}}} = \frac{0.94 - 0.98}{\sqrt{\frac{0.98 \times 0.02}{250}}} = -4.51$$

$$\therefore |Z_{\text{cal}}| = 4.51$$

Critical value: The tabulated value of Z at 0.10 level of significance

is $Z_{0.10} = -1.28$ (since this is one tailed-left so we see the value inside table)

$$\therefore |Z_{0.10}| = 1.28$$

Decision: $|Z_{\text{cal}}| = 4.51 > |Z_{0.10}| = 1.28$, So, H_0 is rejected, i.e., H_1 is accepted.

Conclusion: Hence we can conclude that students submitted their assignment is less than 98%.

Q. Hypothesis testing of difference of two population proportion:

Problem to test:

$$\text{Null Hypothesis } (H_0) : P_1 = P_2$$

i.e., There is no significance difference between two population proportion.

$$\text{Alternate Hypothesis } (H_1) : P_1 \neq P_2$$

i.e., There is significance difference between two popⁿ proportion.

$$\text{OR } P_1 < P_2$$

$$\text{OR } P_1 > P_2$$

Test Statistics:

$$Z_{\text{cal}} = \frac{P_1 - P_2}{\sqrt{\hat{P}\hat{Q}\left(\frac{1}{n_1} + \frac{1}{n_2}\right)}}$$

where, P_1 = Sample proportion drawn from 1st population. $\text{OR } P_1 = \frac{x_1}{n_1}$

P_2 = Sample proportion drawn from 2nd population. $\text{OR } P_2 = \frac{x_2}{n_2}$

$$\hat{P} = \frac{n_1 P_1 + n_2 P_2}{n_1 + n_2} \Rightarrow \frac{x_1 + x_2}{n_1 + n_2}$$

$$\hat{Q} = 1 - \hat{P}$$

Q. At a certain date in a large city 400 out of a random sample of 500 men were found to be smokers. After the tax on tobacco had been heavily increased, another random sample of 600 men in the same city included 400 smokers. Test at 5% level of significance.

Solution:

Sample - Ist

$$\text{Sample size } (n_1) = 500$$

$$\text{no. of smoker } (x_1) = 400$$

$$\text{Sample proportion of smoker } (P_1) = \frac{x_1}{n_1}$$

$$= \frac{400}{500} = 0.8$$

$$\text{level of significance } (\alpha) = 5\% = 0.05$$

Sample - IInd

$$\text{Sample size } (n_2) = 600$$

$$\text{no. of smoker } (x_2) = 400$$

$$\text{Sample proportion of smoker } (P_2) = \frac{x_2}{n_2}$$

$$= \frac{400}{600} = 0.67$$

Problem to test:

Null Hypothesis (H_0): $P_1 = P_2$.

i.e., There is no significance difference between the population proportion of smokers after tax is increased.

Alternate Hypothesis (H_1): $P_1 > P_2$

i.e., There is decrease in proportion of smokers after tax is increased.

Test Statistics:

Here,

$$\hat{P} = \frac{X_1 + X_2}{n_1 + n_2} = \frac{400 + 400}{500 + 600} = 0.727$$

$$\hat{Q} = 1 - \hat{P} = 1 - 0.727 = 0.273$$

Now,

$$Z_{\text{cal}} = \frac{P_1 - P_2}{\sqrt{\hat{P}\hat{Q}\left(\frac{1}{n_1} + \frac{1}{n_2}\right)}} = \frac{0.8 - 0.67}{\sqrt{0.727 \times 0.273 \left(\frac{1}{500} + \frac{1}{600}\right)}} \\ = 4.81$$

Critical value: The tabulated value of Z at 0.05 level of significance is $Z_{0.05} = 1.64$ (One-tailed test).

Decision: Since $Z_{\text{cal}} = 4.81 > Z_{\text{tab}} = 1.64$, So, H_0 is rejected.
i.e., H_1 is accepted.

Conclusion: Hence we can conclude that there is decrease in number of smokers after heavily increase in tax.

i.e., sample size < 30 .

④ Hypothesis testing of single population mean (for small sample):

Test Statistics:

$$t_{\text{cal}} = \frac{\bar{X} - \mu}{\frac{s}{\sqrt{n}}} \quad \left. \begin{array}{l} \text{where, } s \text{ is sample standard deviation} \\ = \sqrt{\frac{1}{n-1} \sum (\bar{x} - \bar{\bar{x}})^2} \\ = \frac{1}{\sqrt{n-1}} \left[\sum x^2 - n \bar{x}^2 \right] \end{array} \right\}$$

If we use deviation then,

$$= \frac{1}{n-1} \left[\sum d^2 - \bar{d}^2 \right] \quad \text{where, } d = x - A$$

If s is given then s is said to be biased estimate.

If s is calculated then s is said to be unbiased estimate.

and $t_{cal} = \frac{\bar{X} - \mu}{\frac{s}{\sqrt{n-1}}} \quad (\text{if } s \text{ is given})$.

Critical value:

The tabulated value of t at α level of significance with $n-1$ degree of freedom (d.f.) is $t_{\alpha, n-1}$.

Q1. Rainfall records of a particular place for last 12 years for the month of July showed that average rainfall at the place was ~~less than 500~~ 500mm and standard deviation of 30mm. Do you agree that the average rainfall at the place was less than 512mm? Use 10% level of significance.

Solution:

Sample size (n) = 12

Average rainfall (\bar{X}) = 500

Sample standard deviation (s) = 30

level of significance (α) = 10% = 0.10

Population average rainfall (μ) = 512

Problem to test:

Null Hypothesis (H_0): $\mu = 512$

i.e., Average rain is 512mm.

Alternate Hypothesis (H_1): $\mu < 512$

i.e., Average rain is less than 512mm.

Test Statistics:

$$t_{cal} = \frac{\bar{X} - \mu}{\frac{s}{\sqrt{n-1}}} = \frac{500 - 512}{\frac{30}{\sqrt{11}}} = -1.326$$

$\therefore |t_{cal}| = 1.326$

Critical value

$t_{0.10, (11)} = -1.363$ (one-tailed test)

$\therefore |t_{tab}| = 1.363$

$t_{\alpha, n-1}$ form

left tailed H.R.L - ve ओरांटी

page no 318 table value

Decision: Since $t_{cal} = 1.326 < t_{tab} = 1.363$, So, H_0 is accepted. i.e. H_1 is rejected.

Conclusion: Hence average rain is 512mm.

Q2. Ten patients are selected at random from a population of patients and their blood pressure recorded as follows;

125, 147, 118, 145, 140, 128, 155, 150, 160, 149.

Do the data support the hypothesis that the population average blood pressure of patients is 135? Use 5% level of significance.

Solution:

Given, Sample size (n) = 10

records of blood pressure of 10 patients (X); 125, 147, 118,

145, 140, 128, 155, 150, 160, 149.

level of significance (α) = 5% = 0.05

Problem to test:

Null Hypothesis (H_0): $\mu = 135$

i.e., The population average of blood pressure of patient is 135

Alternate Hypothesis (H_1): $\mu \neq 135$.

i.e., The population average of blood pressure of patient is not 135.

Test statistics:

$$t_{cal} = \frac{\bar{X} - \mu}{\frac{s}{\sqrt{n}}}$$

Now the value of s is not given so we calculate it using given data as follows:-

X	$d = X - A$ $= X - 140$	d^2
125	-15	225
147	7	49
118	-22	484
145	5	25
140	0	0
128	-12	144
155	15	225
150	10	100
160	20	400
149	9	81
$\sum d = 17$		$\sum d^2 = 1733$

Here,

$$\begin{aligned} \text{Mean } (\bar{X}) &= A + \frac{nd}{n} \\ &= 140 + \frac{17}{10} \\ &= 141.7 \end{aligned}$$

$$\text{and } s = \sqrt{\frac{1}{n-1} [\sum d^2 - \bar{d}^2]}$$

$$= \sqrt{\frac{1}{9} [1733 - 10 \times \left(\frac{17}{10}\right)^2]}$$

$$= 13.76.$$

since $\bar{d} = \frac{\sum d}{n}$

Now,

$$t_{\text{cal}} = \frac{141.7 - 135}{13.76 / \sqrt{10}}$$

$$= 1.53$$

Critical value: The tabulated value of t at $5\% = 0.05$ level of significance. $(n-1)$ degree of freedom is,

$$t_{0.05, (9)} = 2.262 \quad (\text{for two-tailed test})$$

Decision: Since $t_{\text{cal}} = 1.53 < t_{\text{tab}} = 2.262$. So, H_0 is accepted. i.e., H_1 is rejected.

Conclusion: The average population of blood pressure of patient is 135.

Q3. A random sample of size 25 showed a mean of 65 inches with a standard deviation of 25 inches. Determine 98% confidence intervals for the mean of the population.

Solution:

Here, Sample size (n) = 25, sample mean (\bar{X}) = 65, sample SD (s) = 25
confidence limit ($1-\alpha$) = 98% = 0.98, level of significance (α) = 0.02

$$\begin{aligned} \text{Confidence limit for } 98\% & \bar{X} \pm t_{\alpha/2, (n-1)} \cdot \frac{s}{\sqrt{n-1}} \\ & = 65 \pm 2.492 \times \frac{25}{\sqrt{25-1}} \\ & = 65 \pm 12.717 \end{aligned}$$

Taking -ve sign,
 $65 - 12.717 = 52.283$

Taking +ve sign,
 $65 + 12.717 = 77.717$

Hence confidence limit is 52.283 inches to 77.717 inches.

Q4. A random sample of size 16 has the sample mean 53, the sum of the square of deviation taken from the mean value is 150. Can this sample be regarded as taken from the population having 56 as its mean at 99% confidence limit?

Solution:

Given,

The sum of square of deviation taken from mean $\sum (x-\bar{x})^2 = 150$.

Sample mean (\bar{x}) = 53.

Population mean (μ) = 56.

Problem to test: Sample size (n) = 16.

Null Hypo (H_0): $\mu = 56$.

i.e., population average is 56.

Alternate Hypo (H_1): $\mu \neq 56$ i.e., population average is not equal to 56.

Test Statistics:

$$t_{\text{cal}} = \frac{\bar{x} - \mu}{\frac{s}{\sqrt{n}}}$$

$$\text{where, } s = \sqrt{\frac{1}{n-1} \sum (x-\bar{x})^2}$$

$$= \sqrt{\frac{150}{15}}$$

$$= 3.16$$

$$\therefore t_{\text{cal}} = \frac{53 - 56}{\frac{3.16}{\sqrt{16}}} \\ = -3.79$$

$$|t_{\text{cal}}| = 3.79$$

Critical value: The tabulated value of t at $1\% = 0.01$ level of significance and $(n-1)$ degree of freedom is,

$$t_{0.01, (15)} = 2.947 \text{ (two-tailed test)}$$

Decision: $|t_{\text{cal}}| = 3.79 > t_{\text{tab}} = 2.947$, So, H_0 is rejected.
i.e., H_1 is accepted.

Conclusion:- Hence, at 99% level of significance confidence limits are;

$$\bar{x} - t_{0.01, (15)} \times \frac{s}{\sqrt{n}} \leq \mu \leq \bar{x} + t_{0.01, (15)} \times \frac{s}{\sqrt{n}}$$

$$\text{or, } 53 - 2.947 \times \frac{3.16}{\sqrt{16}} \leq \mu \leq 53 + 2.947 \times \frac{3.16}{\sqrt{16}}$$

$$\text{or, } 50.672 \leq \mu \leq 55.328$$

Q. Hypothesis testing of difference of two population mean (for small sample):

Problem to test:

Null Hypothesis (H_0): $\mu_1 = \mu_2$

Alternate Hypothesis (H_1): $\mu_1 \neq \mu_2$

OR $\mu_1 < \mu_2$

OR $\mu_1 > \mu_2$

Test Statistics

$$t_{\text{cal}} = \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{s_p^2 \left(\frac{1}{n_1} + \frac{1}{n_2} \right)}}$$

where, s_p^2 is the pooled (combined) variation and calculated as,
 $s_p^2 = \frac{n_1 s_1^2 + n_2 s_2^2}{n_1 + n_2 - 2}$ when s_1 and s_2 are given (i.e., biased).

$$s_p^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2} \quad \text{when } s_1 \text{ and } s_2 \text{ are not given (i.e., unbiased).}$$

Critical value

The tabulated value of t at α level of significance with $n_1 + n_2 - 2$ degree of freedom is; $t_{\alpha/2, (n_1 + n_2 - 2)}$.

Examp Q. Two kinds of manure were applied to sixteen one hectare plot, other condition remaining the same. The yields in quintals are given below;

independent samples

Manure I	18	20	36	50	49	36	34	49	41
Manure II	29	28	26	35	30	44	46		

Is there any significant difference between the mean yields?
Use 5% level of significance.

Solution:

Given, sample size (n_1) = 9, Sample size (n_2) = 7

level of significance (α) = 5% = 0.05

Problem to test

Null Hypothesis (H_0): $\mu_1 = \mu_2$ i.e., there is no significance difference between the mean yields.

Alternate Hypothesis (H_1): $\mu_1 \neq \mu_2$ i.e., there is significance difference between the mean yields.

Test Statistics

$$t_{cal} = \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{s_p^2 \left(\frac{1}{n_1} + \frac{1}{n_2} \right)}}$$

for the calculation of s_1^2 , s_2^2 , \bar{X}_1 and \bar{X}_2

Manure I (X_1)	$d_1 = X_1 - A_1$ $= X_1 - 36$	d_1^2	Manure II (X_2)	$d_2 = X_2 - A_2$ $d_2 = X_2 - 35$	d_2^2
18	-18	324	29	-6	36
20	-16	256	28	-7	49
36	0	0	26	-9	81
50	14	196	35	0	0
49	13	169	30	-5	25
36	0	0	44	9	81
34	-2	4	46	11	121
49	13	169			
41	5	25			
	$\sum d_1 = 9$	$\sum d_1^2 = 1143$		$\sum d_2 = -7$	$\sum d_2^2 = 393$

Now, $s_1 = \frac{1}{n_1-1} \left[\sum d_1^2 - \bar{d}_1^2 \right] = \frac{1}{8} \left[1143 - \left(\frac{9}{9} \right)^2 \right] = 142.71$

$$s_2 = \frac{1}{n_2-1} \left[\sum d_2^2 - \bar{d}_2^2 \right] = \frac{1}{6} \left[393 - \left(\frac{-7}{7} \right)^2 \right] = 65.33$$

$$\text{Mean } (\bar{X}_1) = A + \frac{\sum d_1}{n_1} = 36 + \frac{9}{9} = 37$$

$$\text{or Mean } (\bar{X}_2) = A + \frac{\sum d_2}{n_2} = 35 + \frac{-7}{7} = 34$$

Here,

$$\begin{aligned} s_p^2 &= \frac{(n_1-1)s_1^2 + (n_2-1)s_2^2}{n_1+n_2-2} \\ &= \frac{(9-1) \times (142.71)^2 + (7-1) \times (65.33)^2}{9+6-2} \\ &= 109.57 \end{aligned}$$

Now,

$$t_{cal} = \frac{\bar{X}_1 - \bar{X}_2}{\sqrt{s_p^2 \left(\frac{1}{n_1} + \frac{1}{n_2} \right)}} = \frac{37 - 34}{\sqrt{109.5 \left(\frac{1}{9} + \frac{1}{7} \right)}} = 0.568$$

Critical value: The tabulated value of t at 0.05 level of significance with n_1+n_2-2 degree of freedom is
 $t_{0.05, (14)} = 2.145$ (two-tailed test).

Decision: Since $t_{\text{cal}} = 0.568 < t_{\text{tab}} = 2.145$. So, H_0 is accepted.
I.e., H_1 is rejected.

Conclusion: Hence we can conclude that there is no significance difference between the mean yields.

④ Paired t-test:

In t-test we have two independent samples but in paired t-test there are two dependent samples of size $n \leq 30$.

For testing the hypothesis we can make the following hypothesis.

Null Hypothesis (H_0): $\mu_{x} \neq \mu_y$ (OR $\mu_y = \mu_x$)

Alternate Hypothesis (H_1): $\mu_x \neq \mu_y$

OR $\mu_x < \mu_y$

OR $\mu_x > \mu_y$

where, x is before value
 y is after value.

(we can use any notation)

Test Statistics:

$$t_{\text{cal}} = \frac{\bar{d}}{s_d / \sqrt{n}}$$

where, $d = x - y$ or $y - x$

x → represent before value

y → represent after value

$$\bar{d} = \frac{\sum d}{n} = \sqrt{\frac{1}{n-1} (d - \bar{d})^2}$$

$$s_d = \sqrt{\frac{1}{n-1} [\sum d^2 - \bar{d}^2]}$$

If n = no. of pairs.

Critical value:

The tabulated value of t at α level of significance with $n-1$ degree of freedom is $t_{\alpha/2, n-1}$.

Q1. A certain stimulus administered to each of the 12 patients resulted in the following increase of blood pressure:

5, 2, 8, -1, 3, 0, -2, 1, 5, 0, 4 and 6.

Can it be concluded that the stimulus will in general be accompanied by an increase in blood pressure.

Solution:

Here,

$$d = X - Y$$

$$n = 12$$

d	5	2	8	-1	3	0	-2	1	5	0	4	6	$\sum d = 31$
d^2	25	4	64	1	9	0	4	1	25	0	16	36	$\sum d^2 = 185$

$$\bar{d} = \frac{\sum d}{n} = \frac{31}{12} = 2.58$$

$$S_d = \sqrt{\frac{1}{n-1} [\sum d^2 - \bar{d}^2]} = \sqrt{\frac{1}{11} [185 - (2.58)^2]} = 3.08$$

Problem to test:

Null Hypothesis (H_0): $\mu_1 = \mu_2$ (or $\mu_{G1} = \mu_{G2}$)

Alternate Hypothesis (H_1): $\mu_1 < \mu_2$ (or $\mu_{G1} < \mu_{G2}$)

Test statistic:

$$t_{cal} = \frac{\bar{d}}{S_d / \sqrt{n}} = \frac{2.58}{3.08 / \sqrt{12}} = \frac{2.58 \times 3.46}{3.08} = 2.89$$

Critical value: Let $\alpha = 0.05$ be the level of significance, then critical value for one tailed test is,

$$t_{tab} = t_{0.05, (11)} = 1.8$$

Decision: $t_{cal} = 2.89 > t_{tab} = 1.8$. So, reject H_0 at 5% level of Significance. i.e., H_1 is accepted.

Conclusion: The stimulus in general be accompanied by an increase in blood pressure.

(Imp) Q.2 - Ten students were given a test in SPSS. Then they were given a month's training and another test was held. The marks obtained by the 10 students in the two tests are given below;

S.N. of students	1	2	3	4	5	6	7	8	9	10
Test I	12	15	10	13	18	10	8	17	9	7
Test II	12	17	12	12	14	12	16	16	18	12

Test whether the students have benifited by the training or not.

Solution

Here, Sample size (n) = 10.

Students	Marks in test I (X)	Marks in test II (Y)	$d = X - Y$	d^2
1	12	12	0	0
2	15	17	-2	4
3	10	12	-2	4
4	13	12	1	1
5	18	14	4	16
6	10	12	-2	4
7	8	16	-8	64
8	17	16	1	1
9	9	18	-9	81
10	7	12	-5	25
$\sum d = -22$				$\sum d^2 = 200$

$$\bar{d} = \frac{\sum d}{n} = \frac{-22}{10} = -2.2$$

$$S_d = \sqrt{\frac{1}{n-1} [\sum d^2 - \bar{d}^2]} = \sqrt{\frac{1}{9} [200 - (-2.2)^2]} = 4.1$$

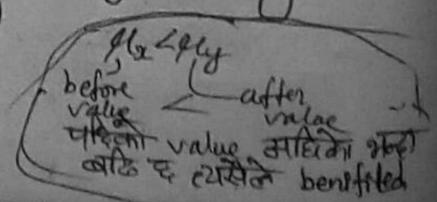

Problem to test:

Null Hypothesis (H_0): $\mu_x = \mu_y$

i.e. Students have not been benefited by training.

Alternate Hypothesis (H_1): $\mu_x < \mu_y$. (One-tailed test)

i.e. Students have benefited by training.

Test Statistic:

$$t_{\text{cal}} = \frac{\bar{d}}{\frac{s_d}{\sqrt{n}}} = \frac{-2.2}{\frac{4.1}{\sqrt{12}}} = -1.69$$

i.e. $|t_{\text{cal}}| = 1.69$.

Critical value:

Let $\alpha = 5\%$ be the level of significance, then critical value for one tailed test is

$$t_{\text{tab}} = t_{0.05, (11)} = 1.83$$

Decision $|t_{\text{cal}}| = 1.69 < t_{\text{tab}} = 1.83$, So, H_0 is accepted at 5% level of significance.

i.e. H_1 is rejected.

Conclusion: The students have not benefited by the training.
